

E2: decodability of tree stats from z_t alone
(validation, real 400K-tree materialized cache)

Plain-English finding: z_t carries only a weak-to-moderate echo of tree shape ($R^2=0.07-0.17$, above the shuffle floor but far below the $R^2 \sim 1$ a trivial readout of the raw stats gets) -- the encoder loses most of this basic structural information rather than preserving it.
